The artificial lift has a new watcher

Permian Resources told investors on November 4th that its production team has deployed an AI-powered artificial lift monitoring system. The pump jack is drawn to illustrate.

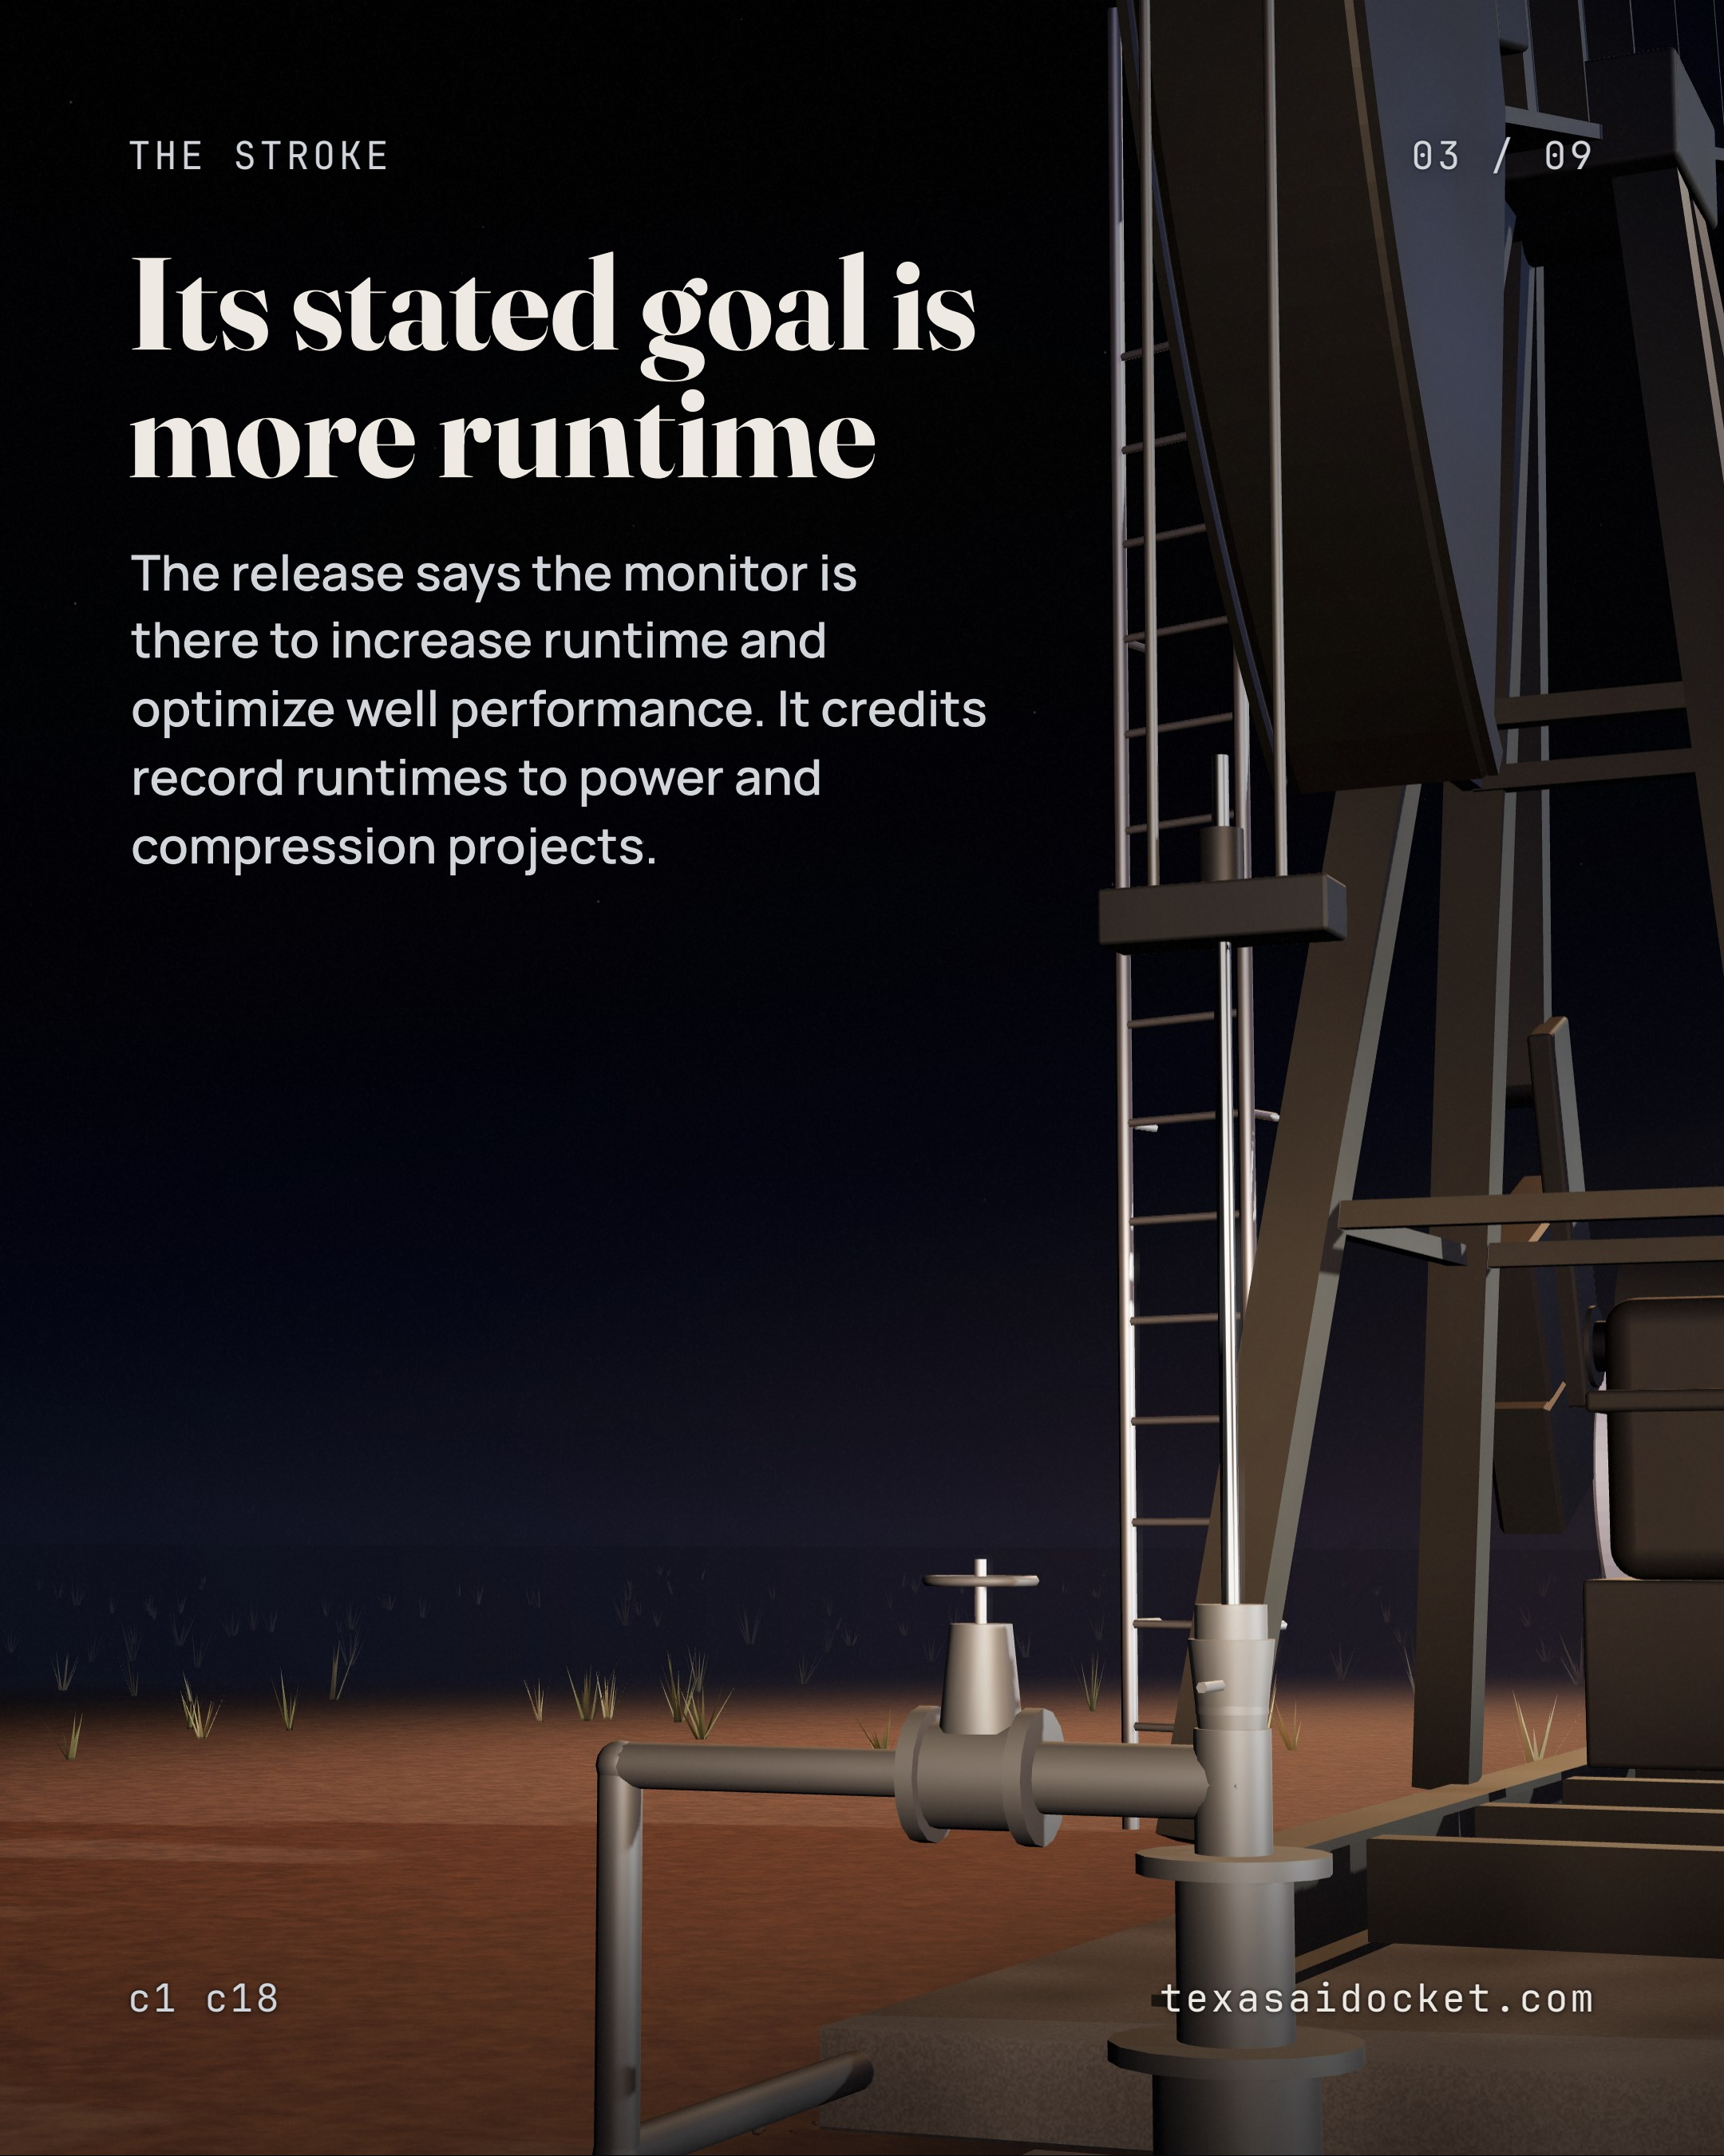

Two AI tools, one earnings release

One monitors its artificial lift. The other feeds its subsurface data into large language models to evaluate wellbore placement and optimize drilling parameters.

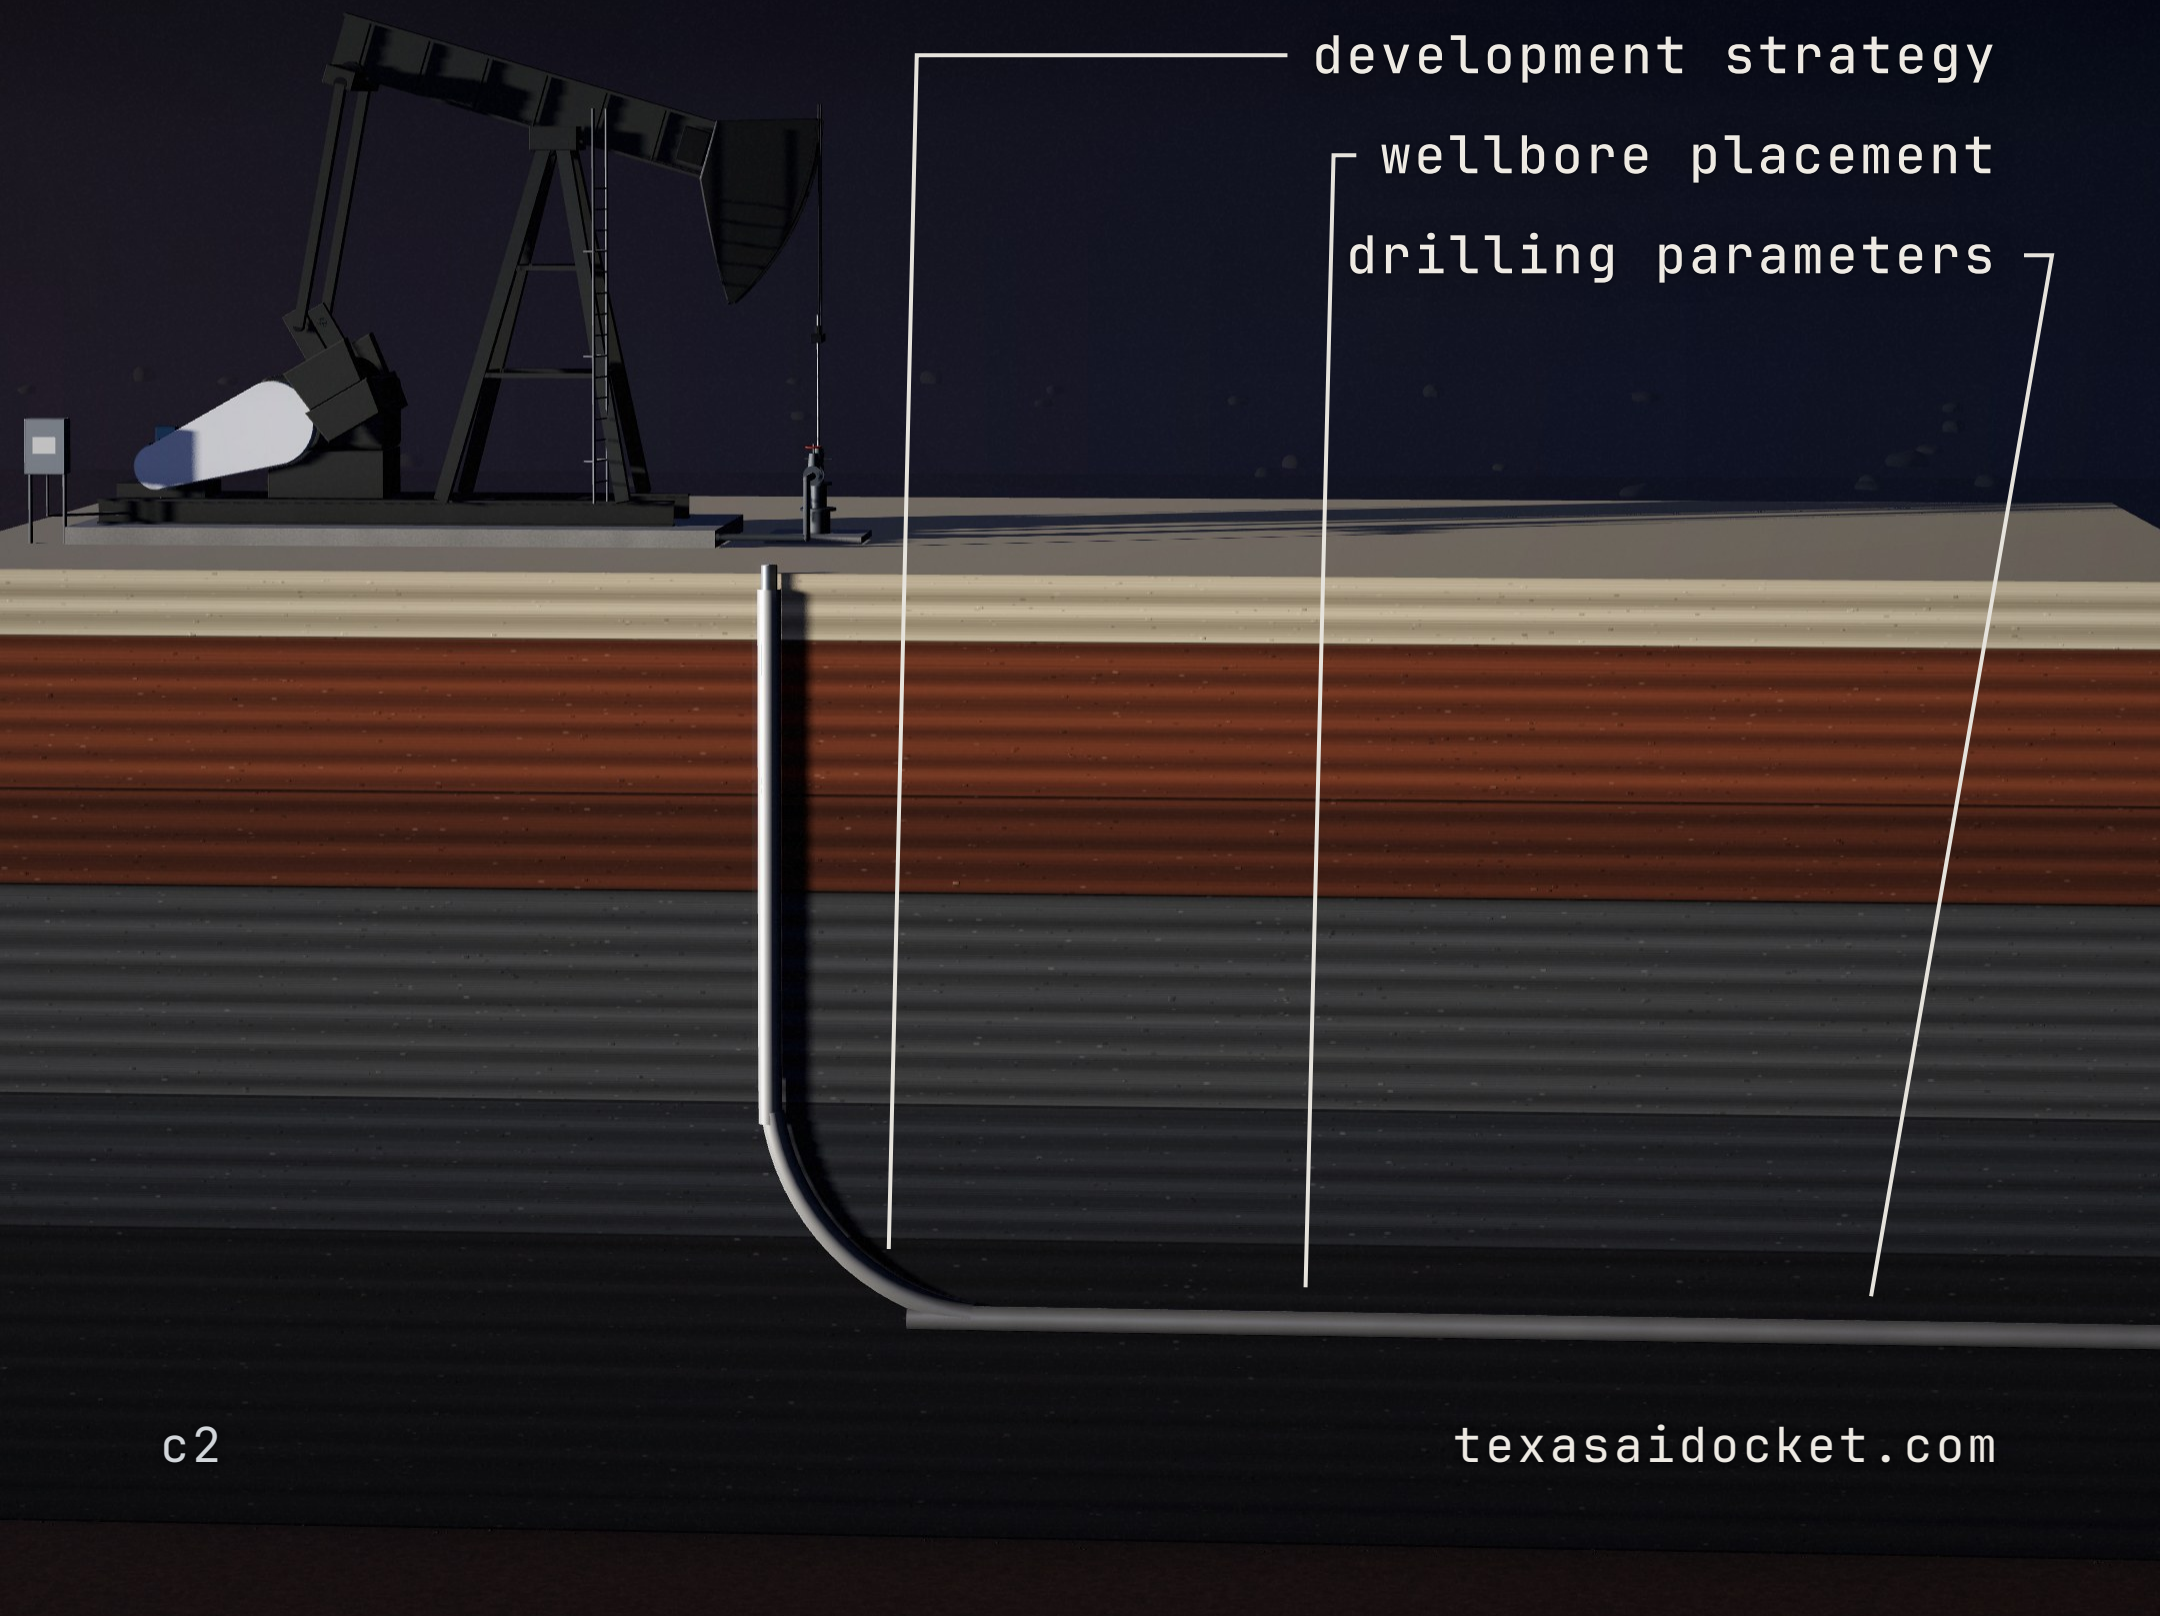

Its stated goal is more runtime

The release says the monitor is there to increase runtime and optimize well performance. It credits record runtimes to power and compression projects.

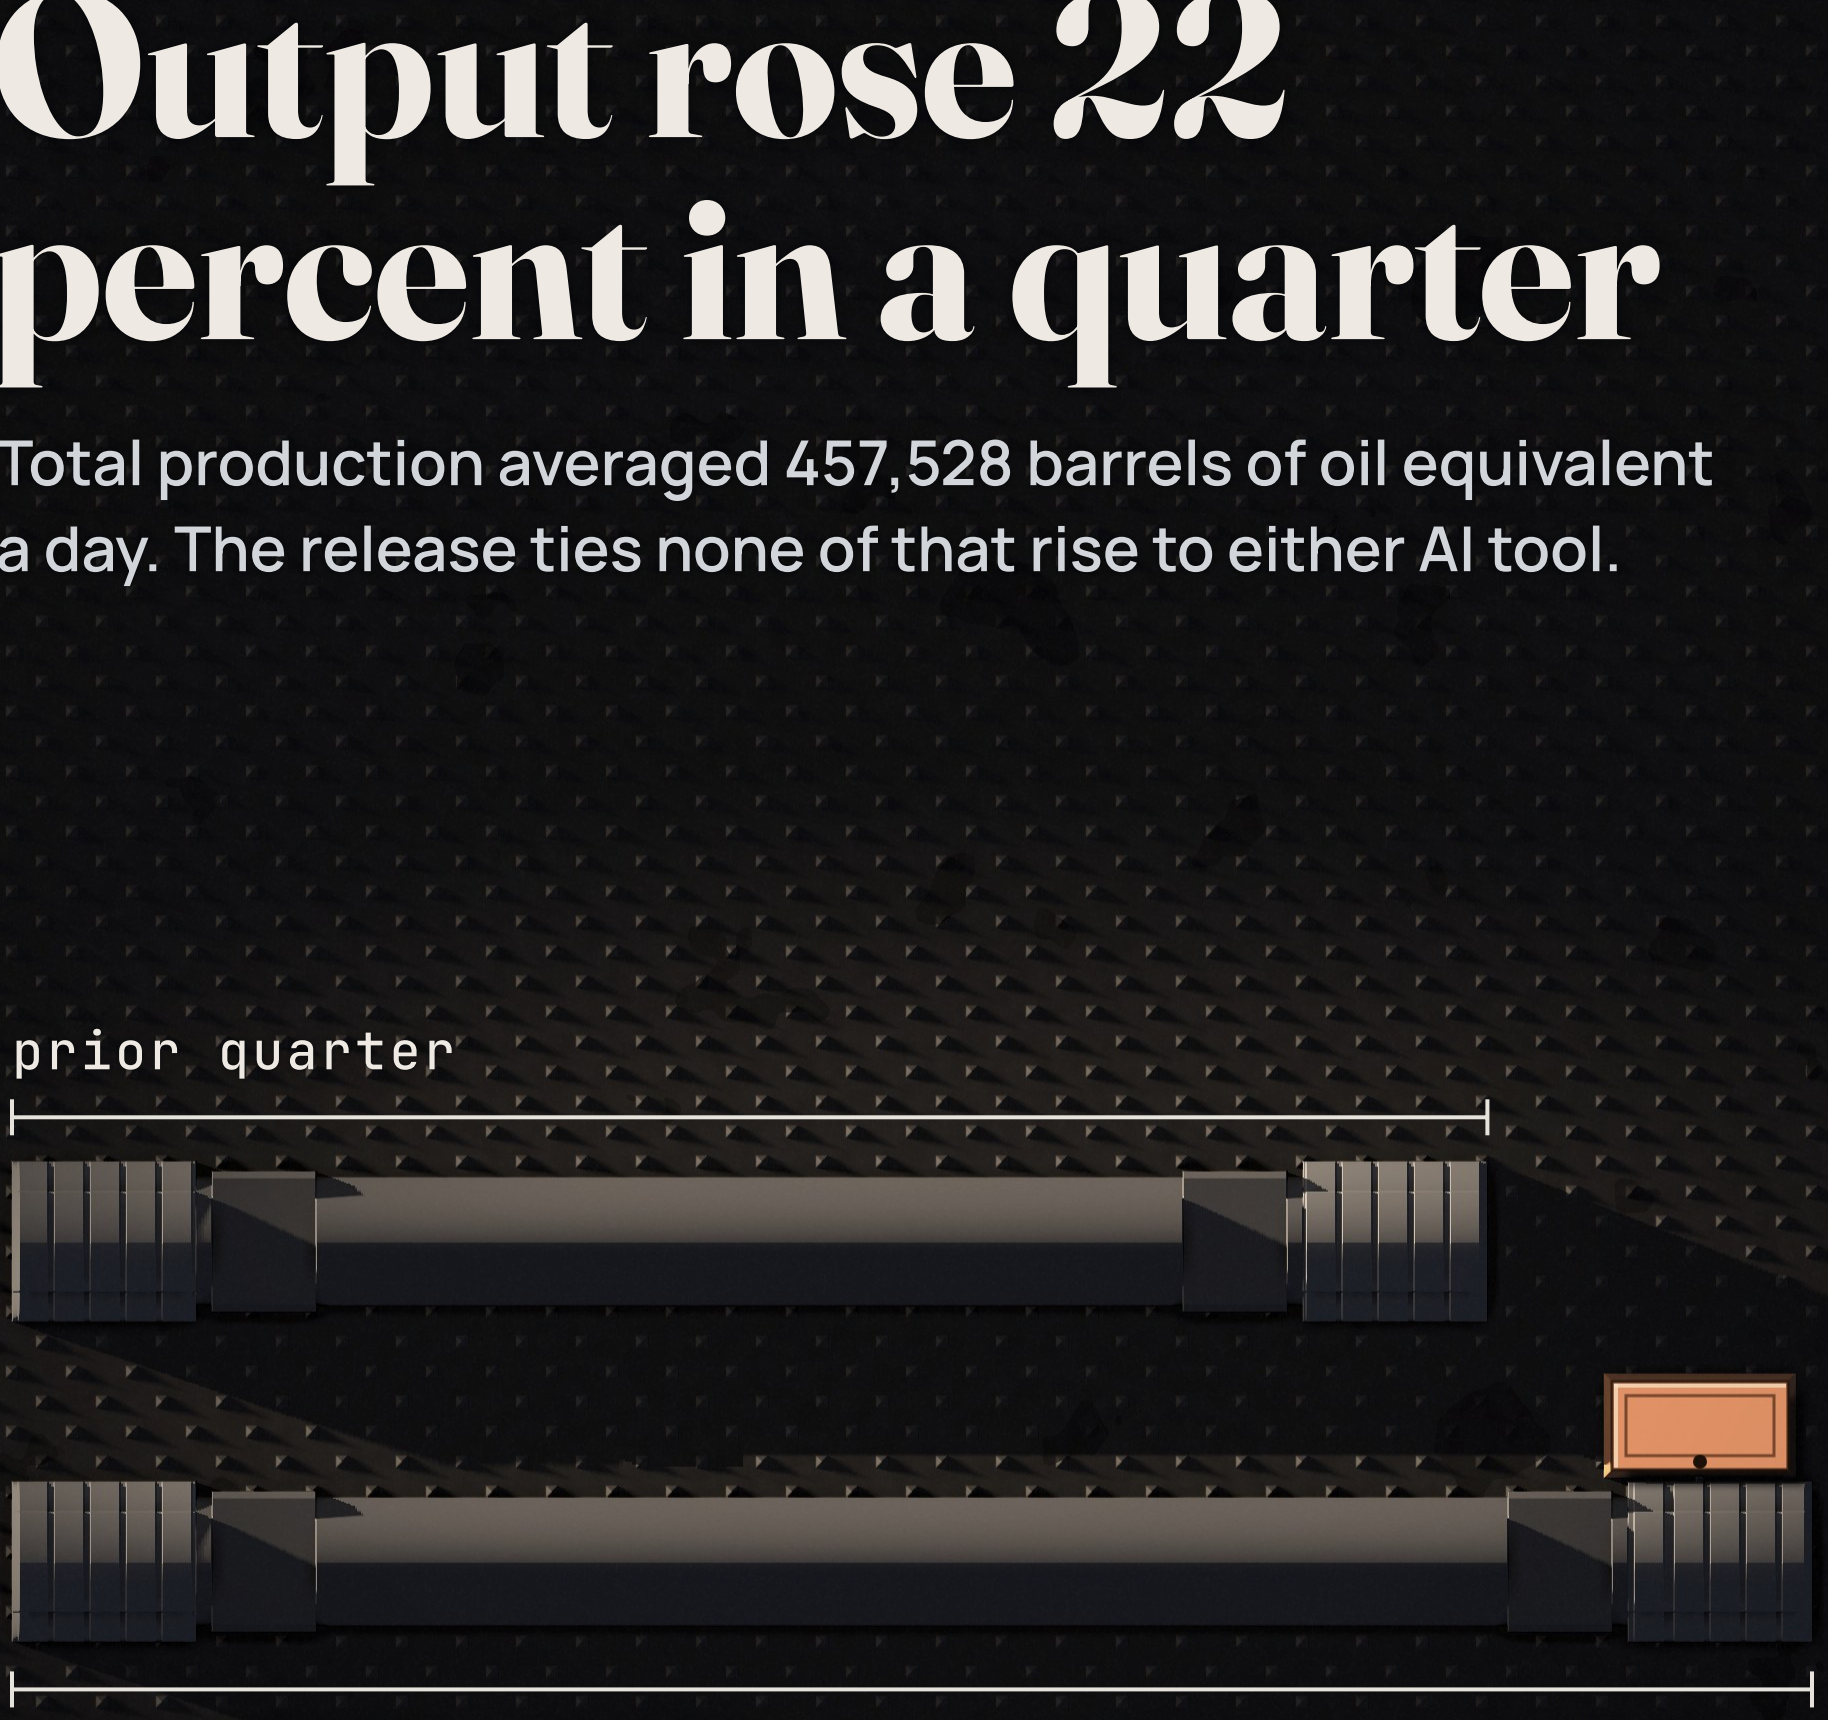

Language models, aimed at the wellbore

The release says the company is combining its subsurface data with large language models. The bands are drawn to illustrate and are not to scale.

Output rose 22 percent in a quarter

Total production averaged 457,528 barrels of oil equivalent a day. The release ties none of that rise to either AI tool.

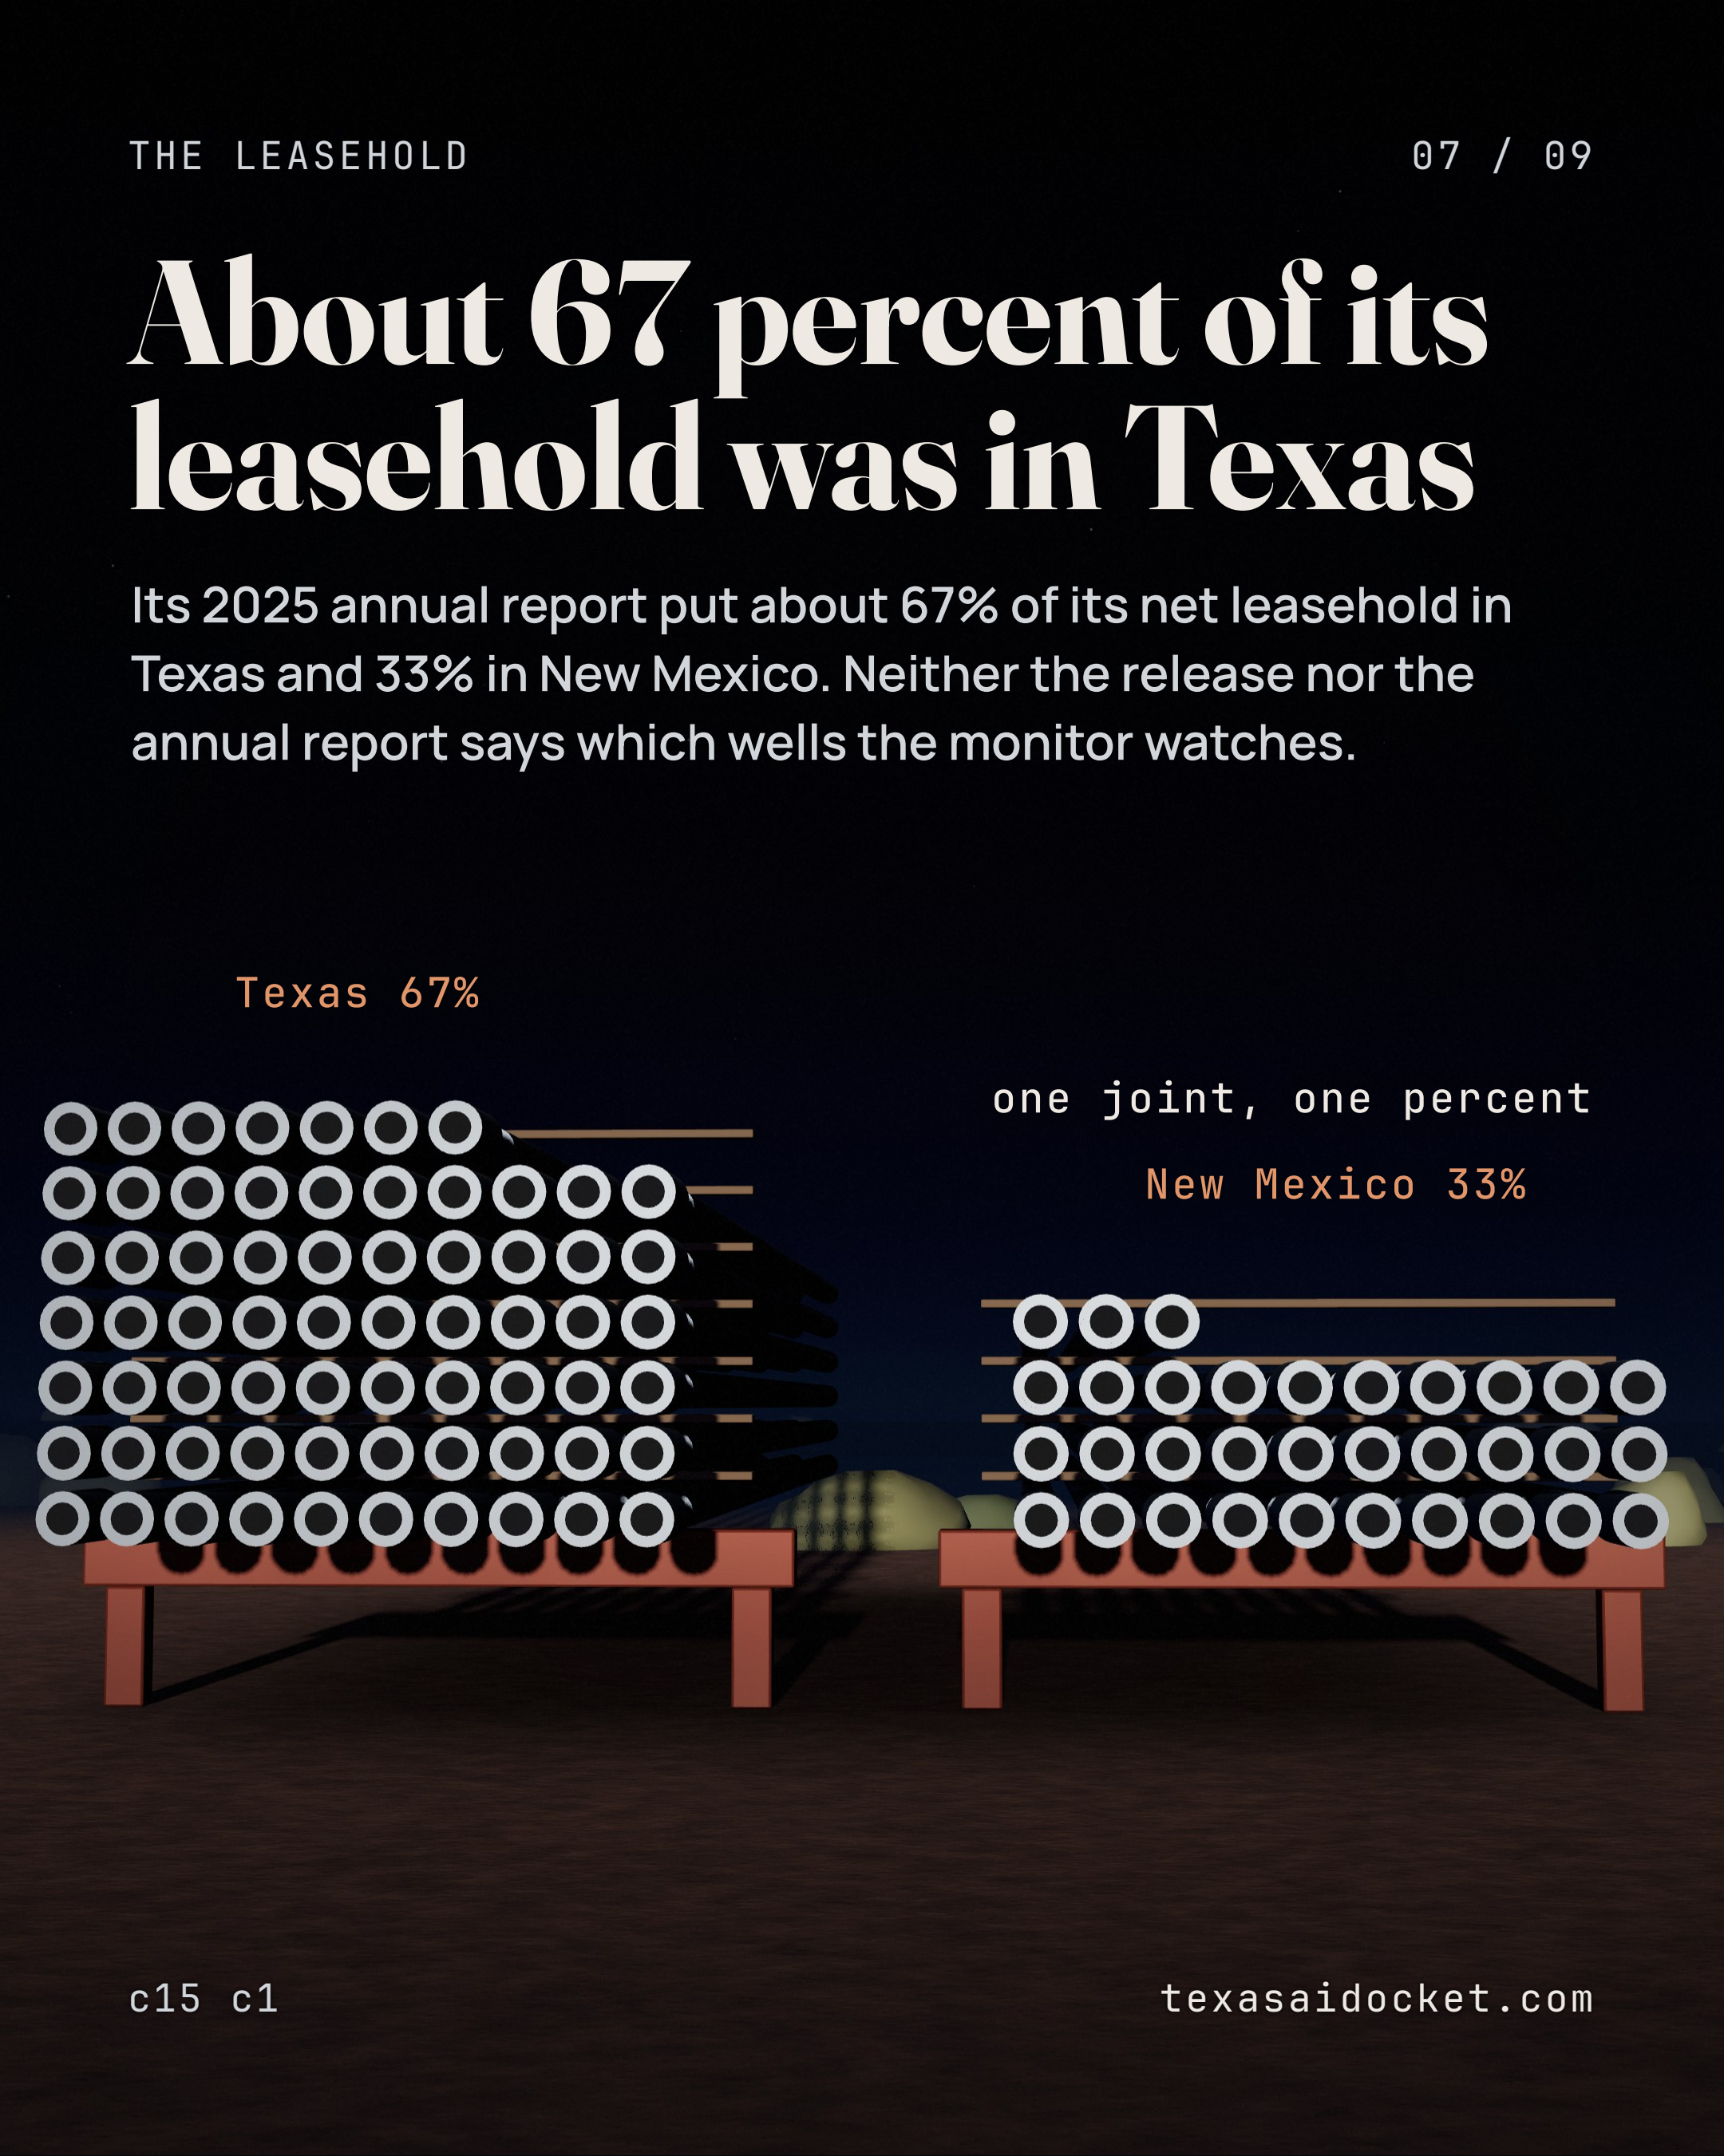

Crude is a little under half of its output

Crude oil averaged 208,029 barrels a day in the third quarter. The gauge's target sits at that share of everything the company produced.

About 67 percent of its leasehold was in Texas

Its 2025 annual report put about 67% of its net leasehold in Texas and 33% in New Mexico. Neither the release nor the annual report says which wells the monitor watches.

The regulator was not aware of any AI use

On May 21st the Texas Tribune reported the Railroad Commission said it was not aware of any use of AI by oil and gas companies. The release came 167 days later.

Who checks what the watcher finds?

The release names two AI tools and prints no measured result for either. The Railroad Commission's next open meeting is November 17th.
